Chronic obstructive pulmonary disease (COPD) is a disease that is associated with life-threatening airway inflammation. Recent efforts have identified COPD-associated gene signatures in airway epithelium and fibroblasts isolated from patients with COPD. These analyses highlight the importance of gene dysregulation as a major mechanism of COPD pathogenesis. However, only a small percentage of the total number of genes in these signature gene sets are linked to COPD pathogenesis. These signatures may include disease phenotypes as well as therapeutic targets. In this chapter, we describe an approach to develop a systems biology strategy for identifying COPD-associated genes and pathways. This approach includes the application of systems biology, proteomics, bioinformatics, and cell-based assays for identification of key signaling molecules that are relevant to the development of COPD. We present a methodology to compare genome-wide proteomic changes in mouse lung tissue and airway epithelial cell lines in response 570a42141b
